

Distortions to Cotton Sector Incentives in West and Central Africa

John Baffes

World Bank
jbaffes@worldbank.org

Paper presented at the CSAE conference “Economic Development in Africa” March 19-20, 2007, Oxford, U.K.

This is a product of a research project on Distortions to Agricultural Incentives, under the leadership of Kym Anderson of the World Bank’s Development Research Group. The author is grateful for helpful comments from workshop participants and for funding from World Bank Trust Funds provided by the governments of Ireland, Japan, the Netherlands (BNPP) and the United Kingdom (DfID). The author would like to thank Kym Anderson for providing numerous comments and suggestions on earlier drafts, Gerald Estùr for providing most the data, and Marianne Kurzweil for performing statistical analysis.

Distortions to Cotton Sector Incentives in West and Central Africa

John Baffes

Introduction and summary

Following decades of development efforts, cotton became the dominant cash crop in most WCA (West and Central Africa) countries. Apart from suitable agro-climatic conditions, the increase in cotton production reflected the vertically-integrated structure of the sector—similar in all WCA cotton-producing countries—which circumvented the free riding risks that would have otherwise constrained its performance.

The WCA cotton sectors share a number of similarities. The industries were pioneered by the French state-owned company CFDT (*Compagnie Française de Développement des Fibres Textiles*)—renamed to DAGRIS (*Développement des Agro-Industries du Sud*) in 2001—in conjunction with national state-owned cotton companies, which had a legal monopsony in cotton buying, and most had a monopoly on primary processing, marketing, and supplying inputs.¹ Typically, the companies would announce a base buying price before planting, sometimes supplementing that price with a second payment (payable in the following season as a bonus) based on the company's financial health. Most cotton used to be marketed through COPACO (*Compagnie Cotonnière*), a CFDT subsidiary. The cotton industries also benefited from research carried out by the French Agricultural Research Institute CIRAD (*Centre de Cooperation Internationale en Recherche Agronomique pour le Développement*) (see Table 1 for key institutions involved in the cotton sectors of WCA countries).

All WCA countries are also similar in that they share a common currency, the CFA franc (CFAf) which is fixed against the euro.² Consequently, their cotton industries (along with the other export-oriented sectors) enjoy the benefits (or suffer the consequences) of the Euro/US\$ exchange rate fluctuations. Moreover, the fact that the CFAf is fixed against the euro, often leads to episodes of misalignment. For example, the overvaluation of the CFAf during the early 1990s

had adversely affected the competitiveness of the export sectors in all WCA countries. In 1994 the CFAf was devalued against the French Franc, thus temporarily restoring the currency equilibrium and competitiveness of the cotton industries.

The objective of this paper is to review the cotton sector policies and reform efforts of Benin, Burkina Faso, Cameroon, Chad, Côte d'Ivoire, Mali, Senegal and Togo and examine the nature and degree of distortions to incentives.³ These countries account for almost all WCA cotton output which is equivalent to about 3.5 percent of global production. The period under consideration spans 1970 to 2005. During this period the prices received by growers in all eight countries have been remarkably stable, fluctuating between CFAf 150 and 200 per kilogram of seed cotton (in real 2000 terms). Given the high variability of world prices, the gap between world and domestic prices reflects, for the most part, world price movements.

This paper argues that there have been four periods with distinct but also similar characteristics in all eight countries. First, during 1970-84 the cotton sectors were heavily taxed with growers receiving 40 percent of the world price (ranging from a low of 30 percent in Mali to a high of 42 percent in Cameroon). The second period spans 1985-93 and was characterized by low world prices and an overvalued currency with growers in the region averaging 55 percent of the world price. The cotton companies faced severe financial difficulties during the end of that period and they had to be rescued repeatedly through budgetary support measures. The third period begins with the devaluation of the CFAf in 1994 and ends in 1997 when the East Asian financial crisis caused the commodity price collapse (including cotton). In some respects this period mirrors the first period in terms of high world price and the low share received by growers (42 percent of world price). Similarly, the last period, 1998 to present, is a mirror image of the 1985-93 period, characterized by low world prices, growers receiving a relatively high share of world price (59 percent), the CFAf being (most likely) overvalued, and most cotton companies facing financial difficulties. The similarities between second and fourth period extend to the consideration of policy reforms; the key difference is that during the second period policy reforms called for restructuring the cotton companies while current policy reforms call for privatizing them.

The rest of the paper is structured as follows. The next section discusses the stylized facts of the WCA cotton sectors. The third section outlines the reasons why the reform efforts currently under consideration should be deepened. The subsequent section gives summary descriptions

of the history and structure of each cotton sector along with the (limited) reform efforts. The penultimate section makes a quantitative assessment of the distortions, while the last section concludes.

Stylized facts of the WCA cotton sectors

The performance of the WCA cotton industries has been viewed as a success story (Lele *et al* 1989). Indeed, between 1970 and 1988, WCA cotton yields grew at 6.1 percent per annum, which compared to the 1.9 percent annual growth in world yields implies that if trends continued, WCA yields would have been similar to world yields by the early 1990s. Moreover, cotton production in WCA increased 10-fold during the last 35 years, from a little over 100,000 tons in 1970 to one million tons in 2005. In the eight WCA countries studied here, cotton provides income to more than 1.5 million households, equivalent to some 10 million people. During 2001-03, cotton contributed 10 percent to the region's merchandize exports and 2.1 percent to the region's GDP.

Yet, the seemingly successful performance of the industries masked a number of weaknesses that called into question their long term sustainability. First, the post-1980 production increase solely reflects area expansion (in contrast to pre-1980 which reflected yields increase, mainly in response to fertilizer use). A growth decomposition analysis for the 1980-2005 period reveals that cotton yields in WCA countries remained (statistically) stagnant (see Figures 1 and 2). In fact, yields in six of the eight countries declined (Table 3). This compares unfavorably with the 1.7 percent annual growth rate of global cotton output, which is a reflection of yield increases only (see bottom panel of Table 3).

Second, growers received low prices even when world prices were high (Figures 3-10). For example, during the early 1980s, WCA cotton producers were receiving 60-70 CFAf per kilogram for their seed cotton while the A Index ranged between (the equivalent of) 200 and 250 CFAf.⁴ (For a description of the world price of cotton, often referred to as the A Index, see Appendix A.) Similarly, following the 1994 devaluation of the CFAf, producer prices were adjusted upwards but far less than the increase in world price, thus denying WCA cotton growers the high prices enjoyed by cotton producers elsewhere. Furthermore, econometric evidence shows that in none of the eight countries did the pricing mechanism reflect movements in the world price of cotton. Three OLS regressions for each country of domestic cotton prices on the A Index (based

on 1970-2005 annual data) yielded price coefficients not significantly different from zero (with the exception of Cameroon and to a lesser extent Senegal), as shown by the parameter estimate for β_1 in Table 4.⁵ Stating the econometric evidence otherwise, the price-setting mechanisms have largely ignored world market signals. This is ironic considering that the various price formulae devised to determine the price to be paid to growers by the cotton companies, use as their starting point the world price of cotton.

Third, while the panterritorial pricing mechanism, common to all WCA countries, is a convenient and socially popular income redistribution mechanism, in effect it transfers resources from efficient cotton growers (or growers with transportation and/or location advantages) to less efficient ones. This common price within each country has thus constrained overall growth and innovation in the industry by penalizing the most productive entities (or areas) of the sector.

Fourth, in periods of price declines most cotton companies experienced financial difficulties which in turn led to demands for fiscal transfers from government budgets, thus putting into jeopardy the fiscal position of these countries. For example, during the late 1990s the cotton company of Mali was in no position to manage the downturn in cotton prices because the stabilization fund, created to set aside a portion of profits from earlier periods of high prices, turned out to be empty, resulting in financial losses of CFAf 56 billion (\$100 million).⁶ Eventually, the cotton company was bailed out. Similar bailouts took place in most WCA countries following the two cotton price collapses—in the mid-1980s and in the late 1990s.⁷

Fifth, because of their inefficient and inflexible structure, the cotton companies were not sufficiently prepared (in terms of improved sales strategies, risk management tools, and adoption of new technologies) to respond to the changing nature of the external environment, especially the downward trend and volatile nature of world prices—a reflection of technological changes and to some extent subsidies by some countries.⁸ For example, consider that more than one third of global cotton output is now of genetically modified origin. Yet, with the exception of Burkina Faso, none of the WCA countries has allowed even field trials to assess the likely benefits and risks of such technology.⁹ Furthermore, recent research has shown that the benefits of fully utilizing biotechnology may be even higher than the benefits from the elimination of all cotton trade distortions (Anderson, Valenzuela, and Jackson 2006).

Finally, because the CFAf is fixed against the euro (or the French franc prior to 1999) and has been subjected to only one adjustment since 1948—from CFAf 50 to CFAf 100 per FF

in 1994—it often leads to unintended consequences. This is not surprising, given the different structure of the euro zone economies compared to those of the WCA countries.¹⁰ Therefore, not only the WCA countries have been unable to adjust their currencies in accordance to the external environment they faced, cotton growers have been adversely affected by the recent weakness of the dollar against the euro. Consider, for example, that during 2005/06 the US\$ A Index average was roughly the same as in 2000/01. However, during the same period the CFAf appreciated from 731 CFAf/\$ to 535 CFAf/\$, effectively reducing the world price of cotton in CFAf terms by 37 percent. Within the current political and macroeconomic setting it is beyond the control of individual WCA governments to choose the exchange rate regime that is consistent with the structure of their economies—but that makes the case for reforms even stronger, because the governments have one less policy tool at their disposal.

The case for deepening current reform efforts

Faced with these constraints, a number of WCA countries began reassessing the structure of their cotton industries. With financial and technical assistance from the donor community, especially the IMF and the World Bank, policy reforms were contemplated in order to bring the cotton sector back to a sustainable development path and, ultimately, increase the welfare of cotton growers. However, because the reforms were portrayed as ideologically driven, they were viewed with suspicion and, not surprisingly, were subjected to considerable opposition from the countries themselves as well as by outside interests.¹¹

In a survey of the cotton sectors of Mali, Burkina Faso, and Benin, Bourdet (2004, p. 41) described the reasons for such opposition as follows: “There are two reasons behind this limited ownership of home government. The first is the strong opposition on a part of the urban elite and some farmer associations in cotton-producing countries to the privatization of the state-owned ginning enterprises, which are at the centre of the network of institutions and actors composing the cotton sector. The second is the opposition of some bilateral donors, in particular France as the main bilateral donor, to the deregulation of the sector. No doubt this ‘lack of enthusiasm’ on the part of the home government of cotton-producing countries and some bilateral donors has contributed to the slow pace and mixed outcome of reforms.”

Following the price collapse of the late-1990s, however, it became evident that reforming the cotton industries and letting the private sector to undertake some of the industry’s activities

is, perhaps, the only feasible alternative.¹² This view was shared, to various degrees, by multilateral and bilateral donors as well as the countries themselves. For example, Edwards (2000, p. 2) concluded that “It is encouraging to note that the sometimes acrimonious nature of the recent debate with regard to the future of cotton in the Francophone producing countries appears to be giving way to a more constructive dialogue, even if consensus on all issues remains elusive.”

Despite the understanding and “constructive dialogue” policy reforms have been limited while the paths to reforms are quite diverse, as the following summary of the eight countries indicates. Reforms in Benin, which were undertaken ‘by function’, consist of three key elements: (i) separation of the various links in the cotton supply chain according to the different functions (input provision and distribution, seed cotton production, transport, ginning, and trading); (ii) division of the responsibility for handling these functions among a large number of actors—except for research and extension, which was considered a semi-public good that needed to be jointly funded by the private and public sectors; and (iii) organization of the key decision making process (including issues such as the price setting mechanism and cotton delivery time) into horizontally organized entities, which must all agree before any sector-wide decision is made.

The reform process in Burkina Faso was undertaken ‘by region’, in a sense reflecting the view that free riding risks of the cotton sector are high, especially with regards to the provision of inputs (and hence credit recovery) as well as research and extension services. The market is currently structured into three regional monopsonies—a dominant state-owned company accounting for about 90 percent of cotton purchases and two private companies, accounting for the rest.

Cameroon has not undertaken any reforms. The cotton company is still the key player of all aspects of the industry. However, during the past few years, producers through their umbrella organization have been in a position to influence considerably the decision making process, especially price determination. Privatization of the cotton company was considered in 1994 and again in 2003 but it never went beyond the discussion stage.

In Chad reforms can be characterized, perhaps, as non-existent. Although the government of Chad announced that it would disengage from the cotton sector in 1999, with the single exception of the privatization of the cotton oil company, so far it has failed to act accordingly. Factors behind the unwillingness to reform include the fiscal difficulties of the cotton company (and hence limited interest by the private sector), the lack of ownership of reform by the government,

and more recently the windfall revenue from crude oil which has practically absorbed all capacity and energy by officials who, otherwise, would have been in charge of the reform process.

Côte d'Ivoire undertook reforms in 1998 when the cotton company was broken into three entities, two privately- and one publicly-owned. However, the performance of the sector has been constrained by the civil war. The Northern part of the country where most cotton is produced has been practically cut off from the South, the point of export. Not surprisingly, substantial quantities of cotton go unrecorded to neighboring Burkina Faso and Mali where producers receive a higher price compared to what the companies in Côte d'Ivoire pay.

Mali, which has contemplated reforms for quite some time, reconsidered its reform commitment in July 2004 and decided to proceed cautiously by carefully assessing the pros and cons of the reform process in other WCA countries. In November 2005, the government increased its share in the capital of the cotton company (from 60 to 70 percent) and publicly announced that reforms will be delayed for several years.

Senegal's cotton sector went through reforms in 2003, when 51 percent of the cotton parastatal's shares were transferred to DAGRIS while an additional 30 percent was given to producers.

In Togo, which has not undertaken any comprehensive reforms, the structure of its cotton sector is less rigid compared to the other countries. Half of Togo's cotton is privately ginned on behalf of the publicly-held cotton company (the remaining is ginned by the cotton company). As is the case with Cameroon, the government does not interfere much with the sector in the sense that it neither directly taxes it nor supports it in periods of low prices. Discussions for reforms have been held recently but no specific action plan has been proposed.

Details of each country's policies

One can safely argue that cotton reforms in WCA countries are far less advanced compared to reforms undertaken by cotton producing countries in Eastern and Southern Africa. This section summarizes the structure of the cotton sectors along with the key elements and reform processes of the eight countries under consideration.

Benin

During 2001-03 cotton contributed 37 percent to total merchandise exports and almost 5 percent

to GDP for Benin. An estimated 325,000 households depend on cotton cultivation, implying that the livelihoods of nearly 2 million people are directly linked to the industry's performance. The average cotton plot in Benin is about one hectare while the typical household produces 450 kilograms of cotton lint, generating roughly \$330 in gross income. Cotton in Benin is a rainfed crop. Two thirds of cotton growers prepare their land manually and some fertilizer and chemicals are used.

Although Benin has a long tradition in cotton cultivation, which started well before the colonial period, it became a commercial crop in 1952 when CFDT introduced a high-yielding cotton variety. Following independence in 1960, CFDT expanded its operations in Northern Benin while another French state-owned company SATEC (*Société d'Aide Technique et de Coopération*) introduced cotton in Central Benin. Towards the end of the 1960s, numerous Village Associations (*Groupements Villageois*) were formed specializing in input distribution, credit provision, and marketing.

Under the leftist regime of the 1970s, a new parastatal was created and took over all activities of the sector. In 1975 six rural development agencies were created—corresponding to the six provinces—with the responsibility of handling input supply and extension services. On the other hand, responsibility for ginning operations was given to another company. Despite the changes, the sector performed dismally. During 1976-81 cotton output averaged 7,000 tons, 8,000 tons less than the corresponding average during 1970-75 (see table B1 in appendix B). Following renewed interest by the government, all cotton-related activities were transferred to the new parastatal SONAPRA (*Société Nationale pour la Promotion Agricole*) in 1984, while numerous cotton development projects were introduced. In the meantime, the relationship with CFDT improved with the acceptance of limited technical assistance.

Reforms were first contemplated in the early 1990s mainly in response to an earlier crisis. Following an exceptionally good crop cotton output increased from 34,000 tons in 1985 to 48,000 tons in 1986. However, the existing ginning operations were unable to process all cotton, leading SONAPRA to incur considerable financial losses. Moreover, the decline in the world price of cotton (from \$1.52/kg in 1985 to \$1.08/kg in 1986) along with the appreciation of the CFAf (from CFAf 378/\$ to CFAf 316/\$) combined with unchanged producer prices at CFAf 110/kg of seed cotton, further contributed to the losses. Under the Structural Adjustment Program of 1991, the government issued a Letter of Rural Development Policy that envisaged the

transfer of the management of the sector to an interprofessional body based on the principles of a common guaranteed panterritorial price to producers, panterritorial prices for inputs, obligation for producers to sell their cotton to specific ginners, and obligation for ginners to buy all cotton from producers.

As a result of this policy shift the equivalent of 20 percent of input supply activities were privatized in 1993 on a pilot basis, increasing to 80 percent in 1995. SONAPRA eventually withdrew from the input supply market in 2000. A second step included issuing licenses to three new private ginning operations in 1995, followed by several more in 1998. That added 225,000 tons of seed cotton ginning capacity to an existing 335,000 tons by SONAPRA. Yet, the new structure caused numerous conflicts resulting in frequent political interference.

In response, the government created a number of entities, including a cooperative belonging to the Regional Producers Unions, GAGIA (*Coopérative d'Approvisionnement et de Gestion des Intrants Agricoles*), formed in 1998. A second entity, APEB (*l'Association Professionnelle des Egreneurs du Bénin*), was created in 1999 with key responsibility to coordinate activities among gineries. Another organization was established in 1999, AIC (*l'Association interprofessionnelle du coton*) in order manage supply chain-related functions. Finally, CSPR (*Centrale de Sécurisation des paiements et de Recouvrement*) was formed in 2000 with the mandate to recover debts from growers, collect and deliver cotton to ginners, and make payments to producers.

Despite all the changes, it appears that the performance of the sector has not improved. During the 2003/04 season, one quarter of seed cotton was bought by private traders, which meant those farmers escaped the credit recovery scheme set up by CSPR. Consequently, tensions among different actors have escalated. The difficulties faced by the sector can be gauged by the sharp decline in cotton production from 171,000 tons of lint in 2004/05 to 82,000 tons in 2005/06.

Burkina Faso

Cotton is the most important cash crop in Burkina Faso, accounting for almost two thirds of total merchandise exports and contributing 5 percent to the country's GDP in 2001-03. The sector provides income to an estimated 210,000 households, implying that the as many as 1.5 million people are affected by the industry. The average cotton plot in Burkina Faso is a little less than 2 hectares.

Cotton was introduced in Burkina Faso towards the end of the colonial period in order to supply the French textile industry with cotton. The development of the sector was the responsibility of CFDT, which remained in charge until 1975 when it was replaced first by a joint venture between the government and CFDT and in 1979 by the new cotton company, SOFITEX (*La Société Burkinabè des Fibres et Textiles*).

Reforms were first considered in 1991 when, under a Structural Adjustment Program, it was decided that management responsibilities of the cotton sector would be transferred to growers and the cotton company. In 1998 the government reduced its stake in the cotton company by transferring 30 percent of its shares to a producer organization, UNPCB (*Union Nationale des Producteurs de Coton du Burkina Faso*), and 34 percent to DAGRIS (*Développement des Agro-Industries du Sud*). As a second step, a 12-member committee was formed in 1999 in order to coordinate the functions of SOFITEX and UNPCB for activities such as determination of the farmgate price, selling price of inputs, and management of the research program. The committee's representation consists of seven producers, three SOFITEX representatives, and two government representatives. The third step involved the introduction of two private companies in 2004 with exclusivity zones for 8 years, representing about 10 percent of cotton production. In 2006 an umbrella organization was created to coordinate the actions of all three cotton companies.

The reform process in Burkina Faso is being viewed as a success case by other WCA cotton-producing countries (AFD 2004). During the past decade, cotton output in Burkina Faso increased almost five-fold, from 64,000 tons in 1995 to almost 300,000 tons in 2005 (see table B2 in appendix B). Furthermore, Burkina Faso is the only country in Sub-Saharan Africa (apart from South Africa) which is in the process of introducing GM cotton. Yet, the expansion of the sector along with the drying up of the cotton stabilization fund as well the recently revealed € 100 million debt by SOFITEX, may call into question the sector's long term sustainability.

Cameroon

Cotton was introduced in Cameroon in the early 1950s under the aegis of CFDT. Initially, it was cultivated with only limited use of inputs. Following two decades of stagnation, the government promoted the use of inputs, in turn boosting yields from 200 kgs/hectare during the mid-1970s to 500 kgs/hectare during the mid-1980s. Since then cotton production increased consistently to

reach 100,000 tons of lint by 2000 (see Table B3).

Cameroon's cotton sector is managed by SODECOTON (*Société de Développement du Coton du Cameroun*), the cotton parastatal in charge of most aspects of marketing and trade. SOEDCOTON, which was established in 1974, is owned by the government (59 percent), DA-GRIS (30 percent), and a private local company (11 percent). Following the expansion of cotton during the 1980s, numerous village associations were formed and in 1994 they became organized cooperatives following an ADF-financed technical assistance project. In 2000, with the assistance of SODECOTON, these groups created an umbrella organization, OPCC (*Organisation des Producteurs de Coton du Cameroun*) whose role is to represent the interests of cotton producers, especially in the price determination mechanism, and as of 2005, the procurement of inputs.

The privatization of SODECOTON was first discussed by the government in 1994 within the framework of a structural adjustment program. However, the attempt did not materialize in part because of the poor financial shape of the company and in part due to some legal dispute regarding the term of the sale. The issue of privatization was revisited in 2003 but did not go beyond the discussion stage.

Chad

Chad's cotton sector is a major part of the economy, contributing 20 percent to total merchandise exports and 2.4 percent to GDP in 2001-03. The sector is the key source of income to some 200,000 households (or as many as 350,000 according to some sources); with an average household size of 5-6 persons, this amounts to 1.2-1.4 million people. The average cotton plot is about 1.5 hectares. Chad's cotton yields are very low, even by WCA standards (about half the yields in Benin or Burkina Faso).

Cotton cultivation was introduced in 1928 under forced labor conditions—Chad was the first WCA country to cultivate cotton. Production grew steadily to 40,000 tons during the early 1960s, making Chad the leading cotton producer in WCA. During 1970-75, Chad's cotton output averaged 46,000 of cotton lint, almost twice as much as Mali's average of 25,000 tons and three times as much as Benin's and Burkina Faso's average of 15,000 tons.

The cotton company of Chad—Cotonchad—was created in 1971, replacing the earlier parastatal, Cotonfran. The government is the majority shareholder (75 percent), followed by DA-

GRIS (19 percent), and the local private banking sector (6 percent). The key missions of Cotonchad were (and still are) to distribute inputs, purchase and gin seed cotton, and trade cotton through its commercial offices in Paris. Cotonchad faced serious difficulties during the price decline of 1985, which was further exacerbated by a drought. Production declined from 60,000 in 1983/84 to 36,000 tons in 1985/85. It took the sector five years to return to earlier levels of output.

However, financial stress of Cotonchad, the heavy taxation from the government, along with civil war and the war with Libya, imposed a heavy burden on the sector (Azam and Djimtoingar 2002). For example, prices paid to cotton growers fluctuated at the low level of CFAf 80 to 100 between 1983 and 1993 (see table B4 in appendix B). The 1994 devaluation provided temporary relief to the sector, as prices paid to growers increased gradually from CFAf 90 in 1993 to CFAf 195 in 1997 (when cotton output exceeded 100,000 tons that year). However, the boom was short-lived, as world price declines along with mismanagement of the sector and heavy taxation forced Cotonchad to reduce the grower price to CFAf 160.

In response to these developments, the government set up a Cotton Sector Reform Committee in 1999 to evaluate potential reform options. The primary concern of the Committee was improving the incomes of cotton farmers through liberalizing the sector along with improving the performance of producer organizations. In 2002, the oil-soap factory was privatized, but that was the only policy reform. The government, together with Cotonchad, organized a workshop in April 2004 in Ndjamená in order to find ways to improve the financial situation of Cotonchad and boost cotton production. However, undertaking deeper reforms was not placed high on the agenda.

The momentum for reforms has weakened even further following the country's windfall revenue from crude oil, which has affected the cotton reform agenda in two interrelated ways. First, crude oil has displaced cotton as the key source of income for the government. Second, the increased activity in the crude oil sector has practically absorbed all capacity and energy by officials who would (and could) have been in charge of reforms in the cotton sector.

Côte d'Ivoire

Cotton, the third most important export crop after cocoa and coffee, accounted for about 3 percent of Côte d'Ivoire's agricultural exports in 2001-03. There are close to 300,000 cotton grow-

ers in Côte d'Ivoire, each cultivating an average cotton plot of a little less than a hectare. Most of Côte d'Ivoire's cotton production is concentrated in the North of the country, an area under great stress due to the civil conflict.

Until the late 1990s, cotton production and marketing were handled entirely by the CIDT (*Compagnie Ivoirienne de Développement des Textiles*), the cotton parastatal. In October 1998, CIDT was broken into three companies of roughly equal size, each operating in a designated zone (i.e., the companies were geographical monopsonies). The first company, CIDT *Nouvelle*, is active in the South of the country and is owned entirely by the government, which has recently expressed interest in selling 80 percent of its shares to cotton growers. However, the producer's association has not been able to raise the necessary capital to purchase the company. The second company, *Société Ivoire Coton*, which operates in the North-West of the country, is a joint venture between the *Aga-Khan* group and the Swiss-based cotton merchant, *Reinhart*. Finally, the LCCI (*Compagnie Cotonnière Ivoirienne*) is a subsidiary of the Swiss-based *Aiglon* group and is active in the North-East of the country. LCCI constructed a new ginnery during 2002/03, which is operated by the local producers' organization, representing some 130,000 cotton growers. This ginnery is reportedly the largest ginning operation in WCA.

In some respects, the privatization efforts of Côte d'Ivoire's cotton sector has been the most advanced in the sense that two new private companies were allowed to enter the sector. However, even under the new structure, no competition has been introduced since the three companies still offer a panseasonal and panterritorial price while they have the exclusive right to buy cotton within their zone. More importantly, the performance of the sector has been thwarted by the civil conflict, which practically isolated most of the cotton producing areas of the North. There are reports that substantial quantities of cotton are exported unrecorded through neighboring Burkina Faso and Mali. Although it is unclear how much of the crop goes through these countries, considering that the average production of the last three seasons has been about two thirds of what it was during the second half of the 1990s, it is not unreasonable to assume that as much as one third of the crop may be marketed through these countries (see Table B5). This should not be surprisingly since price received by Ivorian cotton growers during the last two seasons has been the lowest among all WCA countries. For example, cotton growers in Burkina Faso received CFAf 210/kg in 2004/05 and CFAf 175/kg during 2005/06. Similarly, in Mali they received and CFAf 210/kg in 2004/05 and CFAf 168/kg in 2005/06. However, the corres-

ponding prices for Côte d'Ivoire were CFAf 185/kg and CFAf 140/kg.

Mali

Cotton is Mali's most important cash crop. During 2001-03 it contributed 30 percent to total merchandise exports and more than 6 percent to the country's GDP. An estimated 300,000 households depend on the crop, which implies that as much as one-third of Mali's population is affected by the sector's performance. The average cotton plot in Mali is 2.6 hectares. As is the case with other WCA countries, cotton is a rainfed crop and most of the land is prepared manually. Cotton is typically rotated with food crops such as millet, sorghum, maize, and groundnuts.

Cotton was introduced in Mali during the late 1940s by CFDT, which continued its involvement even after independence in 1960. A national cotton company, CMDT (*Compagnie Malienne pour le Développement du Textile*), was formed in 1974 as a joint venture between the government (60 percent) and CFDT (40 percent). CMDT has been responsible for the promotion of cotton production and has played a key role in the ownership, management, and control of the different components in the supply chain, including the cotton oil-processing sector. It has also assumed responsibility for rural development, particularly road maintenance and some extension services in the major cotton-growing areas. In addition to CMDT, another organization, OHVN (*Office de la Haute Vallée du Niger*) has been involved in the cotton sector since 1970. OHVN was allocated a specific part of the country to operate and has responsibility for the promotion of all crops. It is involved in all cotton production activities but not in ginning. CMDT which currently owns and operates two ginneries in the OHVN zone is paid by the latter to carry out ginning.

The first comprehensive review of the cotton sector was undertaken in 1989 and to a large degree the sector's current institutional setting reflects that review.¹³ The key steps taken in 1989, which were supported by the donor community, included financial autonomy of CMDT, introduction of minimum producer price, and establishment of a stabilization fund. CMDT's weak management along with the 1999 decline of cotton prices resulted in a financial crisis. In response, CMDT set a low price for the 2000/01 season causing many growers to abandon cotton cultivation. Cotton output declined from 197,000 tons in 1999/2000 to 102,000 tons in 2000/01 (see Table B6 in appendix B). Faced with these difficulties, the government prepared a comprehensive restructuring plan (*Lettre de Politique de Développement du Secteur Coton*), which envi-

saged reforming CMDT's institutional arrangements in order to restore the competitiveness of the sector and ultimately foster broad-based growth. The poor financial shape of CMDT, however, has persisted. Between 1997 and 2004, it generated profits only twice while the losses in 2005 alone amounted to some CFAf48 billion (\$91 million). Yet, the government has publicly announced that it will not engage in any reform effort until 2008.

Senegal

Senegal's cotton sector is very small compared to other sectors and is the smallest WCA cotton producer (excluding Central Africa Republic, Guinea, and Niger.) During 2001-03, the sector contributed 2 percent to merchandize exports and 0.3 percent to the country's GDP. Cotton export earnings during this period averaged a little over \$20 million. There are an estimated 70,000 cotton producing households, cultivating an average cotton plot of less than a hectare.

Cotton was introduced in Senegal after independence. Production increased to 15,000 tons of lint during the mid-1970s and has remained at that level since then. All marketing and trade aspects of the sector were handled by SODEFITEX (*Société de Développement des Fibres Textiles*), a government-owned parastatal. In November 2003, DAGRIS became the majority shareholder of SOEDFITEX (51 percent). Cotton producers acquired 30 percent of the remaining shares, while the government retained 10 percent. Local spinners received the remaining shares.

Cotton is ginned at SODEFITEX's five ginning operations. Although it is too early to assess the reforms, it is noteworthy to note that during the past 4 seasons, Senegal's cotton output averaged 19,000 tons of lint, the highest average of any 4-year period since 1970 (see Table B7). Senegal also managed to pay cotton growers the second highest average real price (after Benin) during 1998-2005.

Togo

Cotton is Togo's second largest export commodity after phosphate fertilizer. It contributed 16 percent to export earnings and 4.2 percent to GDP in 2001-03. Togo's cotton production is in the same range as that of Chad; during 2001-03 it averaged 68,000 tons. Its yields, however, are much higher than in Chad but lower than in Benin, Burkina Faso, and Mali.

Cotton was introduced in Togo relatively recently. For example, during the early 1970s, cotton production averaged only 2,000 to 3,000 tons. In 1974, the state-owned company SOTO-

CO (*Société Togolaise de Coton*) began its operations by handling most of the input supply and marketing activities as well as research, extension and maintenance of the road network (World Bank 1988). Production increased significantly after the 1980s, and exceeded 50,000 tons following the 1994 devaluation (see Table B8 in appendix B).

Togo's cotton sector differs from the other WCA countries in that following the purchase of cotton it sells half of the crop to three private ginneries at a price equal to the price paid to the producers plus marketing and transportation costs. The share of cotton delivered to each ginnery is fixed, set as a proportion to its respective ginning capacity. While Togo's cotton sector was affected by the late-1990s decline in prices, SOTOCO responded quickly by cutting down operating costs and reducing the prices paid to growers. This was the only feasible alternative since there is no stabilization fund in place to cover losses, nor the government's tight financial situation allowed any budgetary support (IMF 2003).

Estimating the Distortions to Cotton Sector Incentives

The task of quantifying the distortions to cotton sector incentives contains elements of both simplicity and complexity. The simple part reflects the fact that there is a well-defined world price indicator, the A Index, one component of which is the cotton of WCA countries (see Appendix A). Since the price of WCA cotton tracks the A Index very closely, one can use it as the world price benchmark.¹⁴ Second, all cotton companies pay panterritorial and panseasonal prices, thus making it is easy to calculate the gap between the world price and prices received by growers. Third, almost all cotton is exported and hence there is no need to deal with domestic marketing distortion issues. Fourth, most of the value of the cotton comes from cotton lint, so calculating the distortion to cotton lint, to a large extent, captures the distortions to the entire cotton market. Lastly, the rate of conversion (i.e., the ginning ratio) between the farm product (cotton seed) and the internationally traded commodity (cotton lint) is a well-known parameter and very similar across countries and years.

However, there are a number of reasons that make quantification of the distortions a complex task. First, in addition to explicit taxation as reflected in the price comparisons, in most cases the governments would 'extract' the profits from the cotton companies without these transfers being explicitly documented. Second, in periods of low prices when the national cotton companies incurred losses, the governments would rescue them through budgetary transfers,

again without explicit documentation. Third, and most importantly, there are numerous inefficiencies inherent in the value chain—especially ginning—making it difficult to distinguish between inefficiencies and taxation. Fourth, often the cotton companies would transfer resources to producers through the provision of public services, such construction and maintenance of rural roads, again very difficult to quantify.

In the context of this paper, the term “distortions to incentives” is defined as the difference between the price received by growers and the price they would receive if there was no implicit or explicit taxation. Quantification of the distortions requires three adjustments to the world price of cotton. First, the fob-cif costs are calculated, which are common to all WCA countries. Second, the inland transportation costs are calculated which are different for each country (higher for land-locked countries and lower for countries with sea-port access). Third, the ginning costs are calculated. While they may be different for each country, the lowest ginning costs are used for all countries, thus implying that both ginning inefficiencies and implicit taxation are two indistinguishable parts of distortions to incentives.

Adjusting the A Index by the cif-to-fob cost consists of two components: international transportation costs (from the export port to the final destination port) and marketing charges. Both of these cost components are common to all countries since international freight rates are the same regardless of the port of origin and destination (see Table B9, Appendix B). Nominal sea freight rates have fluctuated between a low of \$35/ton in 1970/71 to a high of \$120/ton in 1984/85. The second component of cif-to-fob costs is marketing charges. These are standard charges across the industry, 3 percent of the A Index until 2002/03 and 2.6 percent since then. These two costs account for an average of 8 percent of the A Index (see last column of Table B9).

Ginning costs are also reported in Table B9 (third column). They have been calculated as an average of all eight countries and they range between CFAf 50/kg of cotton lint in the early 1970s to more than CFAf 200/kg after the mid-1990s. On average, ginning costs are approximately half compared to the price received by growers. Lastly, domestic transport costs for all eight countries are reported in Table B10. As expected, there are substantial differences between landlocked countries and countries with access to sea ports. Consider for example that it costs CFAf 100 to transport one kg of cotton lint from Chad to the port of Duala while it costs less than half of that for Benin, Senegal, and Togo, which have access to port.

Results of distortions to incentives are reported in Table 5. The first three panels give the period averages for all eight countries on the domestic value of the A Index and price received by producers (both in constant 2000 terms) as well as producer's share. The results confirm the earlier assumption that such share has been low during the first (1970-84) and third (1994-97) periods and much higher during the second (1985-93) and fourth (1998-2005) period. Furthermore, variability of prices received by growers has been much less compared to the price received by the cotton companies, by a factor of 5 to 9 (see penultimate panel of Table 5).

When transport (both domestic and international) as well as ginning costs are accounted for, it appears that, on average, cotton growers have been taxed by 43 percent during 1970-84 and 37 percent during 1994-97 (see lower panel of Table 5). However, they have received subsidies of six and nine percent during 1985-93 and 1998-2005, respectively (for an example of how these figures have been calculated, see Box 1). The heaviest taxation has taken place in Mali, where during the first and third period farmers were taxed at 53 and 44 percent, respectively. On the contrary, the lowest taxation has taken place in Cameroon with rates of 44 and 28 percent during these two periods. It is also noteworthy to mention that the taxation during the first and third periods was consistent across all eight countries as was the subsidization during the last period.

Concluding remarks

This paper reviewed the cotton sector policies and examined the nature and degree of distortions to incentives in eight WCA countries, namely, Benin, Burkina Faso, Cameroon, Chad, Côte d'Ivoire, Mali, Senegal and Togo. These countries account for almost all WCA cotton output, roughly equivalent to 3.5 percent of global production. The period under consideration spans 1970 to 2005.

The paper concluded that during the period under consideration, there have been four sub-periods with similar but also distinct characteristics. First, during 1970-84 the cotton sectors were heavily taxed at an average rate of 43 percent (the highest rate of taxation was in Mali, 53 percent while the lowest was in Cameroon, 44 percent). During the second period, there was no major taxation or subsidization incident; on average, however, the sectors were subsidized at six percent. It is also important to note that during this period the cotton companies faced severe financial difficulties during the end of that period and they had to be rescued repeatedly through

budgetary support measures. During the third period, begins with the devaluation of the CFAf in 1994 and ends in 1997 when the East Asian financial crisis caused the commodity price collapse (including cotton), the sectors were, again taxed, on average, by 37 percent. During the last period, 1998 to present (which in many respects is a mirror image of the 1985-93 period), cotton growers were subsidized by an average rate of nine percent. Note that the last period was characterized by low world prices, the CFAf being (most likely) overvalued, and most cotton companies facing financial difficulties.

ENDNOTES

¹ In addition to their core activity which is ginning, the cotton companies engage in numerous other activities such as input distribution, provision of research and extension services, and maintenance of rural roads.

² The CFA Franc (CFAf) is the common currency of 14 West and Central African countries comprising two groups, members of the Franc Zone. One group includes Benin, Burkina, Côte d'Ivoire, Guinea Bissau, Mali, Niger, Senegal, and Togo which form the West African Economic and Monetary Union (WAEMU) and whose common central bank is the Central Bank of West African States (BCEAO). The other group includes Cameroon, Central African Republic, Congo, Gabon, Equatorial Guinea, and Chad which form the Central Africa Economic and Monetary Community (CEMAC) and whose common central bank is the Bank of Central African States (BEAC). The CFAf was created in 1945, when France ratified the Bretton Woods agreement. At that time, the CFAf was the acronym for Franc of the French Colonies of Africa (*Franc des Colonies Françaises d'Afrique*). In 1958, it became Franc of the French Community of Africa (*Franc de la Communauté Française d'Afrique*). Today it means Franc of the African Financial Community (*Franc de la Communauté Financière d'Afrique*) for WAEMU members and Franc of Financial Cooperation in Central Africa (*Franc de la Coopération Financière en Afrique Centrale*) for CEMAC members. Initially, convertibility with the French Franc (FF) was set at 0.59 CFAf/FF, becoming 0.50 CFAf/FF after the 1948 devaluation of the French Franc. In 1958 two zeros were added to the existing denomination, making it 50 CFAf/FF. In January 1994 it was re-pegged to the French Franc at 100 CFAf/FF and in 1999 it was linked to the euro at 656 CFAf/€.

³ The eight countries studied here account for 99 percent of WCA cotton output. Three minor WCA cotton producers not included here are Central Africa Republic, Guinea, and Niger.

⁴ Cotton refers to cotton lint, sometimes called cotton fiber (the internationally traded commodity). When reference to seed cotton (the farm product) is made, it is explicitly mentioned. The rate of conversion from seed cotton to cotton lint—the ginning outturn ratio—is currently about 42 percent in all WCA countries (i.e., one kg of seed cotton is required to produce 0.42 kgs of cotton lint).

⁵ In the first regression (upper panel), the price received by producers (CFAf, adjusted by the GDP deflator) is regressed on the A Index (also expressed in CFAf, adjusted by the GDP deflator). In the second regression (middle panel), the price received by producers (CFAf, nominal) is regressed on the A Index (CFAf, nominal) and the GDP deflator. In the third regression (lower panel), the price received by producers (CFAf, nominal) is regressed on the A Index (US\$, nominal), the CFAf/US\$ exchange rate, and the GDP deflator. All variables are in logarithms and all regressions include a constant and a time trend. The only significant parameter estimate on price is for Togo (upper panel). Unit root tests, however, showed that the error term is non-stationary, thus indicating poor model performance.

⁶ Despite the poor performance of price stabilization funds and international supply control mechanisms (see Gilbert 1996) there have been renewed calls for such mechanisms. See, for example, discussions in Ravry *et al.* (2006) and OXFAM (2007). The failure of stabilization mechanisms should not be surprising if one considers that during the seven 12-month intervals between March 1995 and March 2002, cotton prices declined six times and remained at the same level once, without experiencing any increase. Under such circumstances, any stabilization fund is likely to go bankrupt no matter how well it is run. Conversely, if prices experience continued increases—a less likely scenario considering their long term downward trend—the stabilization fund is likely to be subject to misuse, as was the case in several WCA countries.

⁷ The 1985 cotton price collapse was a result of a policy shift in US commodity programs (including cotton). It also reflects a policy shift in China that favored cotton production there. The decline in the late-1990s reflects the East Asian financial crisis, again common to most commodities. Nevertheless, cotton has not been part of the recent price boom (see figure 11) with the likely reasons reflecting a combination

of the following: (i) cotton subsidies continue to depress prices considerably; (ii) productivity gains from genetically modified (GM) cotton and other technological advances have kept production costs low, compared to other commodities; and (iii) the price increase in the overall commodity price index is due to the increasing demand of certain commodities for biofuels production (e.g., maize and sugarcane for ethanol and rapeseed for biodiesel).

⁸ For a review of the distortions in the global cotton market see Baffes (2005). The US cotton subsidies were subject to a WTO case brought by Brazil (see Schnepf 2004). Benin, Burkina Faso, Chad, and Mali also brought a case to the WTO demanding compensation from the countries that subsidize their cotton sectors (see Sumner 2006; Anderson and Valenzuela 2006).

⁹ Under the West Africa Regional Biosafety Program, a \$23.4-million World Bank technical assistance operation, the WAEMU countries are expected to establish national and regional biosafety policies and procedures in order to ensure proper assessment of the risks and benefits of biotechnology products (World Bank 2006).

¹⁰ The degree of overvaluation differed markedly among WCA countries. Baffes, Elbadawi, and O'Connell (1999, p. 450-51), for example, based on a single equation framework found that during the early 1990s, the CFaf was overvalued more than 30 percent in Côte d'Ivoire while it was roughly in equilibrium in Burkina Faso. Devarajan (1999, p. 370), based on a simple general equilibrium model, concluded that the CFaf overvaluation in 1993 was: Cameroon (78 percent), Togo (52 percent), Mali (39 percent), Côte d'Ivoire (36 percent), Burkina Faso (9 percent), Benin (3 percent), and Chad (-19 percent, i.e., undervalued).

¹¹ When policy reforms were reconsidered in the mid-1990s, cotton prices were high so the resistance should not come as a surprise. It was after the collapse of cotton prices that reforms were seriously discussed. For a lively debate between the French and the World Bank on WCA cotton reforms see ICAC (1998a and 1998b). The World Bank's views can also be found in Baffes (2001).

¹² Reform strategies in WCA have been discussed in various contexts. See, for example, Pursell (1998), Badiane *et al.* (2002), Goreux (2004), and Baghdadli (2006).

¹³ Developments in the Malian cotton sector were also influenced by an uprising by the cotton farmers in the early 1990s (see Bingen 1998).

¹⁴ In a study that examined the comovement of the various components of the A Index as well as the comovement between the A Index and its components, Baffes and Ajwad (2001) found that the WCA cotton prices tracked the A Index very closely.

BOX 1: Calculating Taxation/Subsidization—Benin in 1970/71

The following example illustrates how the nominal rate of taxation/subsidization for Benin (1970/71 season) was calculated. The nominal price received by cotton growers during 1970/71 was CFAf 34/kg of seed cotton (Table B1, fourth column). The March-July (marketing period) 1971 average of the A Index was \$ 0.69/kg of cotton lint (Table B9, first column). Freight rates and marketing costs were 8.1 percent of the A Index (Table B9, last column), hence the fob value of the A Index was \$ 0.63/kg of lint (i.e. 91.9 percent of \$ 0.69). At an exchange rate of 276 CFAf/\$ (Table B9, second column), the fob price of cotton lint becomes CFAf 174/kg. Domestic transport costs for lint were CFAf 8/kg (Table B10, first column), so the ex-gin price of lint becomes CFAf 166/kg. Ginning and farm-to-gin transport costs for lint were CFAf 50/kg (Table B9, third column), so the farmgate price of cotton lint becomes CFAf 116/kg. Applying the 38.1% ginning outturn ratio (Table B1, fourth column) gives a farmgate cotton seed price of CFAf 44/kg seed. Comparing that to the CFAf 34/kg paid to cotton growers, gives 77 percent or, equivalently, 33 percent taxation. Calculating these values for 1970/71 to 1984/85 and averaging them over the entire period, gives the 57 percent value reported in the upper left cell of the lower panel of Table 5 (or the 43 taxation discussed in the text).

TABLE 1: Key Institutions Involved in the Cotton Industries of WCA Countries

INSTITUTION/ENTITY	STATUS	MAIN FUNCTIONS AND RESPONSIBILITIES
FRANCE		
DAGRIS (<i>Développement des Agro-Industries du Sud</i>)	State-owned	Known as CFDT (<i>Compagnie Française de Développement des Fibres Textiles</i>) prior to 2001, it pioneered the cotton sectors in most WCA countries.
COPACO (<i>Compagnie Cotonnière</i>)	Subsidiary of DAGRIS	Used to trade most of WCA cotton; it currently trades about 5 percent of WCA cotton.
CIRAD (<i>Centre de Cooperation Internationale en Recherche Agronomique pour le Développement</i>)	State-owned	French Agricultural Research Institute responsible for the development of cotton varieties and input packages for WCA countries.
AFD (<i>Agence Française de Développement</i>)	State-owned	Development Agency of France financing projects, especially in Francophone countries.
BENIN		
SONAPRA (<i>Société Nationale pour la Promotion Agricole</i>)	Parastatal	The cotton company of Benin; it used to be responsible for all aspects of the industry. Now it has relinquished control to other entities (see below).
GAGIA (<i>Coopérative d'Approvisionnement et de Gestion des Intrants Agricoles</i>)	Private	It was formed in 1998, a cooperative belonging to the Regional Producers unions. It represents the interests of the cotton companies.
APEB (<i>l'Association Professionnelle des Egreineurs du Bénin</i>)	Private	It was created in 1999 with the key responsibility to coordinate activities among ginneries.
AIC (<i>l'Association Interprofessionnelle du Coton</i>)	Private	It was established in 1999 in order to manage supply chain-related functions.
CSPR (<i>Centrale de Sécurisation des paiements et de Recouvrement</i>)	Private	Created in 2000 with the mandate to recover debts from grower, deliver cotton to ginneries, and make payments to growers.
BURKINA FASO		
SOFITEX (<i>La Société Burkinabè des Fibres et Textiles</i>)	Parastatal	The cotton company of Burkina Faso, with ownership, 36 percent by the government, 30 percent by UNPCE (see below) and 34 percent DAGRIS.
UNPCB (<i>Union Nationale des Producteurs de Coton du Burkina Faso</i>)	Private	Producer organization, which has a strong say on SOFITEX's decisions such as prices received by growers, selling prices of inputs, and management of the research program.
CAMEROON		
SODECOTON (<i>Société de Développement du Coton du Cameroun</i>)	Parastatal	The cotton company of Cameroon; it is owned by the government (59 percent), DAGRIS (30 percent), and a private local company (11 percent).
OPCC (<i>Organisation des Producteurs de Coton du Cameroun</i>)	Private	Umbrella organization of cotton producer groups, established in 2000.
CHAD		
Cotonchad	Parastatal	The cotton company of Chad, in charge all marketing and trade aspects of the industry, including managing direct sales through its Paris-based office.

Continued

TABLE 1: Key Institutions Involved in the Cotton Industries of WCA Countries

INSTITUTION/ENTITY	STATUS	MAIN FUNCTIONS AND RESPONSIBILITIES
CÔTE D'IVOIRE		
<i>CIDT (La Compagnie Ivoirienne de Développement des Textiles)</i>	Parastatal	The cotton company of Côte d'Ivoire, which used to handle all marketing and trade aspects of the industry. Since 1998 it operates in one of the three cotton zones. The other two zones are served by private companies.
MALI		
<i>CMDT (Compagnie Malienne pour le Développement du Textile)</i>	Parastatal	The cotton company of Mali, handling almost all marketing and trade aspects of the cotton industry.
<i>OHVN (Office de la Haute Vallée du Niger)</i>		Company involved in the promotion of many crops, including cotton. It is involved in cotton production (not ginning) in a specific part of the country.
SENEGAL		
<i>SODEFITEX (Société de Développement des Fibres Textiles)</i>	Parastatal	The cotton company of Senegal, which used to handle all aspects of marketing and trade until 2002, when majority shareholding was transferred to DAGRIS.
TOGO		
<i>SOTOCO (Société Togolaise de Coton)</i>	Parastatal	The cotton company of Togo, handling all production and marketing activities of cotton, except ginning half of the cotton crop, which is done in three private ginneries.

Notes: The growth rate has been calculated as $\rho = \exp(\beta) - 1$ from the following regressions: $\log(X_t) = \mu + \beta t + \varepsilon_t$, where X_t refers to production, area, or yield, t is time trend, while ε_t denotes the error term (absolute t -ratios in parentheses); μ and β denote parameters to be estimated. DW, ADF, and PP denote the Durbin-Watson, Augmented Dickey-Fuller, and Phillips-Perron statistics, which complement the conventional statistics in assessing the performance of the models. Asterisks correspond to significance levels of 1% (***), 5% (**), and 10% (*).

1998-2005	309	304	322	291	312	298	316	303
PRICES RECEIVED BY COTTON GROWERS (constant 2000, CFAf/kg of seed cotton)								
1970-84	195	146	208	134	282	172	171	188
1985-93	209	148	178	170	204	156	156	179
1994-97	218	176	198	183	204	168	199	204
1998-2005	190	177	176	161	178	170	183	177
PRODUCER'S SHARE OF THE A INDEX (percent)								
1970-84	38	35	42	34	45	30	35	37
1985-93	56	52	64	53	53	49	55	53
1994-97	45	39	44	40	42	37	43	43
1998-2005	62	59	59	56	57	59	59	59
PRICE VARIABILITY (Z-Statistic)								
A Index	124	116	111	96	150	130	115	135
Domestic	18	19	24	18	26	22	13	19
Ratio	7	6	5	5	6	6	9	7
NOMINAL RATE OF PROTECTION (>100)/TAXATION (<100) (percent)								
1970-84	57	55	66	56	69	47	53	56
1985-93	104	102	133	115	99	96	102	96
1994-97	64	58	72	63	62	56	62	63
1998-2005	109	113	110	114	105	113	104	103

Notes: Price variability (penultimate panel) is the Z-statistic, calculated as: $Z = [\sum_t (P_t - P_{t-1})^2 / (n - 1)]^{1/2}$, where P_t and P_{t-1} denote current and lagged price level while n ($= 35$) is the number of observations. The choice of the specific measure of price variability reflected the fact that prices are non-stationary and hence alternative measures such as variance may give misleading results. Although there is a single A Index price, its different value among countries reflects the adjustment by the domestic GDP deflator. The row titled "Ratio" (penultimate panel) is the ratio of "A Index" to "Domestic"; e.g., for Benin the variability of the world price (expressed in domestic currency terms) has been 7 times higher compared to the variability of the price received by cotton growers (both prices have been expressed in real terms). The lower panel reports the nominal rate of protection or subsidization, which is the price received by growers as a share of the farmgate price, when all costs are taken into consideration.

APPENDIX A: THE COTLOOK A INDEX

The most commonly used world cotton price indicator is the Cotlook A Index. It is an index compiled daily by *Cotton Outlook*, a private company located in Liverpool, UK. Every day, the editorial staff of *Cotton Outlook*, who have no trading involvement in cotton “*establish what they consider to be the representative level of competitive offering rates prevailing in the market for each of the eligible growths.*” The A Index is the average of the 5 lowest quotations of 18 styles of cotton (Middling 1-3/32”), C/F Far Eastern values, from the following origins: Australia, Benin, Brazil, Burkina Faso, China, Greece, India, Côte d’Ivoire, Mali, Pakistan, Paraguay, Syria, Tanzania, Turkey, US (3 types), and Uzbekistan. Quotations from numerous other origins are also reported but do not participate in the A Index.

The index is calculated as the average of the five least expensive quotations to account for the fact that quotations reflect offering prices, not the level at which business has been arranged—a buyer is normally expected to succeed with bids that are lower than quoted. The quotations represent nearby delivery, normally between two and four months. Table A1 depicts the composition of the A Index for 2 and 16 March, 2006.

TABLE A1: COMPOSITION OF THE A INDEX (US CENTS PER POUND)

ORIGIN	March 02, 2006	March 16, 2006	Shipment
01. Australia	NQ	NQ	
02. Benin	59.50*	58.75*	March/April
03. Brazil	62.50	61.00	August/September
04. Burkina Faso	60.25	59.50	March/April
05. China	NQ	NQ	
06. Greece	60.25	59.50	March/April
07. India	55.00*	55.50*	March/April
08. Côte d’Ivoire	60.25	58.75	March/April
09. Mali	59.75*	58.50*	March/April
10. Pakistan	NQ	NQ	
11. Paraguay	61.75	60.75	April/May
12. Syria	60.50	59.50	March/April
13. Tanzania	NQ	NQ	
14. Turkey	NQ	NQ	
15. US (California/Arizona)	66.00	65.25	March/April
16. US (Memphis/Eastern)	60.75	60.00	April/May
17. US (Memphis/Orleans)	59.25*	58.50*	April/May
18. Uzbekistan	59.75*	58.75*	March/April
A INDEX	58.65	58.00	

Notes: NQ indicates no quotation. (*) indicates that the quotation is one of the 5 least expensive and thus eligible for the A Index.

APPENDIX B: DEFINITIONS AND SOURCES OF DATA

This appendix describes the data which cover the 1970-2005 period. The next eight tables (B1-B8) report country-specific data, Table B9 reports cif-to-fob costs figures. Table B11 reports data on cotton production, area, and yields for the WCA and the world. All quantity statistics and prices received by producers refer to crop years while GDP deflators are in calendar years. Seed cotton was converted to cotton lint by using the ginning outturn ratio reported in Tables B1-B8.

All price data refer to 1st grade. Production refers to cotton lint. Data for Benin are from SONAPRA; prices received by growers include bonus (after 1990/91) as well as government subsidies between 2001/02 and 2005/06. Data for Burkina Faso are from SOFITEX; following 1995/96, prices received by growers include bonus. Data for Cameroon are from SODECOTON; following 1994/95, prices include bonus. Data for Chad are from Cotonchad; bonus has been paid in only 4 years. Data for Côte d'Ivoire are from CIDT; prices include bonus after 1995/96. Data for Mali are from CMDT; price include bonus after 1990/91. Data for Senegal are from SODEFITEX; bonus is included in only three years. Data for Togo are from SOTOCO; prices do not include any bonus.

The A Index (reported in Table B9, see appendix A for a description) is taken from the World Bank's Commodity Price database (the original source is *Cotton Outlook*) and has been expressed as March-July average to reflect the marketing season in WCA countries. The CFAf/US\$ exchange rate (March-July average) is taken from the IMF (International Financial Statistics). The Manufacture Unit Value (MUV), used as an inflation proxy for the US\$-based A Index, represents the unit value index in dollar terms of manufactures exported from the G-5—France, Germany, Japan, UK, and the US—weighted in proportion to the countries' exports to developing countries. It is prepared by the World Bank's Development Prospects Group. The GDP deflators for all countries are taken from the IMF (International Financial Statistics) and supplemented by the World Bank's Development Prospects Group estimates prior to 1980.

The sea freight costs, expressed as \$/ton are also reported in table B9 and are the same for all countries since the distance between the WCA sea ports and the ports of North Europe or South-East Asia are roughly the same. In nominal terms, sea freight costs have fluctuated between a high of \$120/ton in 1984/85 and a low of \$35/ton in 1970/71. Marketing costs, also reported in table B9 are typically expressed as percent of the A Index (3 percent until 2002/03 and 3.6 percent afterwards); they have been expressed as \$/ton in Table B9. The last two column of

the table expresses the fob-to-cif costs as a percentage of the A Index. Ginning costs are also reported in Table B9; they represent average ginning costs for the entire WCA. Lastly, domestic transportation costs are reported in table B10 (CFAf/kg of cotton lint, nominal terms). As expected, they vary greatly across countries, with land-locked countries having the highest costs (e.g., Chad) while countries with access to ports having the lowest (e.g., Benin, Senegal, and Togo).

Source: Country sources (see Tables B1-B8), World Bank and IMF (International Financial Statistics).

Notes: The A Index (cotton lint) and the CFAf/\$ exchange rate have been calculated over as a March to July average to account for the fact that most cotton is marketed during this period. Marketing costs have been calculated as 3% of the A Index up to 2002/03 and 2.6% afterwards. Ginning costs are expressed in terms of cotton lint.
